Questions and Answers Analysis Paper in the Biological Sciences. 3? Online Biology Report Writing, Biology Biology Papers Paperwriting Biology Papers, Biology Papers. Glioblastomas (GBMs) are the most common primary brain tumor, with an annual incidence of 3-4/100,000 and a median survival of only 12-15 months from the time of diagnosis (Cairncross, 2001). The short lifespan of GBM patients, despite aggressive management, suggests the need for more aggressive therapeutic interventions. Various strategies have been used to increase survival in patients with GBM. GBM cells are highly invasive with a significant component of invasion that precedes growth of the primary tumor. Tumor progression occurs, in part, as a result of invasion of the extracellular matrix (ECM) surrounding the tumor. Furthermore, invasion of normal brain tissue is a characteristic of GBM tumor progression. The focal adhesion protein paxillin is a key regulator of cell migration and invasion. Paxillin is a component of adhesion complexes, and expression of paxillin is upregulated in most, if not all, invasive tumor cells. Paxillin is directly involved in cytoskeletal anchorage and signal transduction and, in vitro, it regulates the migration and invasion of tumor cells. Paxillin is also a substratum-targeting protein that is expressed in metastatic tumor cells and promotes their invasiveness (Simon, et al.,

---

1998, Proc. Natl. Acad. Sci. 95:1525-1530). In fact, it has been recently observed that paxillin is directly linked with the metastatic process in GBM (Jovanovic, et al., 1999, Science 285:837-840). Paxillin is highly phosphorylated in invasive cells and is a substrate of the tyrosine kinase growth factor receptor p60c-src (Fong and Hanisch, 1997, J
